Authors’ contributions
This work was carried out in collaboration between all authors. Author AUC identified the species of plant, designed the study, wrote the protocol and wrote the first draft of the manuscript. Authors MYD, TSM and MIH managed the literature searches and analyses of the data while, authors AUC, TSM, YAA and USA managed the experimental process. All authors read and approved the final manuscript.

ABSTRACT
A medicinal plant is any plant in which one or more of its organs contain substances that can be used for therapeutic purpose or which are precursors for the synthesis of useful drugs. In this research, six (6) selected plants were screened for antihemorrhoid activities in mice. The extracts

*Corresponding author: E-mail: doccletus@yahoo.com;
were obtained from whole plant or parts of plants such as root, stem, leaves and seeds and include the following plants: *Khaya senegalensis, Anogeissus leiocarpus, Parkia biglobosa, Newbouldia leavis and Prosopis africana*. Hemorrhoid (pile) was induced in a group of five mice of five animals per group using *Jatropha curcas, Euphorbiaceae*(I.P) and using Pilex granule as the control drug. Group I received 10 mg/kg Pilex granule, and 100, 200, 400, and 600 mg/kg b.w of *A. leiocarpus, N. leavis, P. africana*, and KEP for groups II, III, IV and V respectively. *A. leiocarpus* and KEP (mixture of *K. senegalensis, E. hirta* and *P. africana*) showed the highest antihemorrhoidal activities in mice than the other plants and compared with the standard drug Pilex granule. However, all the plant extracts showed significant recto - anal coefficient at potent levels. The study showed that the extracts of the plants investigated possessed antihemorrhoidal activities with *A. leiocarpus* and KEP demonstrating the highest activity in mice.

**Keywords**: Anti-hemorrhoid; medicinal plants; mice; pilex granule; *Jatropha curcas*.  

**1. INTRODUCTION**

Hemorrhoids are abnormal masses of dilated blood vessels in swollen tissue that occurs internally in the anal canal or externally around the anus which may be bleeding, pain or itching. It has been a common and painful human disease for decades. The exact prevalence in most developing countries has not been determined in spite of the growing problems associated with this ailment especially among the local populace in North-east Nigeria States, which are majorly due to dietary habits. This disease is frequently encountered in developing countries [1]. Various dilations of the internal hemorrhoids as well as physiological dilations which exist at infancy, is presumed to have developed into varicosities under the influence of wide range of factors. The predisposing factors include heredity age, anal sex, and prolong labour at pregnancy. The precipitating factors comprise cathartic abuse, diarrhea, enemata, constipation, infection and spasms or a stony dietary intake which put extra pressure on the intestinal mucosa linings which may subsequently result in rupture of the mucosa linings of the small intestine [2].

There are two types of piles, internal piles and external piles. Internal piles expand inside, along the anal. The common symptom of internal pile is the painless blood loss. The internal piles are totally prolapsed. External piles extend close to the anus. The colour of external piles is same as the skin. The outside piles forms thrombus. The outside piles are painful. When the external pile ruptures, it bleeds. The blood loss is more disturbing, and it is the major concern for considering a therapeutic measure by a medical practitioner. Prolapsed condition on the other hand, is an oral dysfunctional effect of piles [3].

Attempt has been made to expel scyballous masses from the rectum by traditional medical practitioners using different plant species using any one or all the following preparations: concoction, decoction and maceration [3].

This research was aimed at evaluating some selected medicinal plants used in North-east Nigeria for the treatment of hemorrhoids with a view to ascertain this claim in traditional medicine, thereby identifying (which of )the plants having the best anti-hemorrhoids activity in mice models.

**2. MATERIALS AND METHODS**

**2.1 Plant Collection and Identification**

The plants species (*Parkia biglobosa, Prosopis africana, Euphorbia hirta, Khaya senegalensis, Newbouldia leavis and Anogeissus leiocarpus*) were collected from Bali and Takum forests in 2016 and were identified by Mr. Cletus A. Ukwubile a taxonomist in Science Laboratory Technology Department, Federal Polytechnic, Bali, where voucher numbers were deposited for the plants.

**2.2 Preparation and Extraction of Plant Materials**

The plants were air-dried for two weeks, grounded into powder, weighed and then stored for onward use. One of the plant (*Newbouldia leavis*) extract was extracted with water following the method of its preparation in traditional medicine while others were extracted with absolute ethanol 99.1% (v/v) and were soaked for 24 hrs using cold maceration technique. The extracts were concentrated to dryness under reduced pressure in rotary evaporator and dried in (a) desiccators. Percentage yields for the
extracts were as follows: Parkia biglobosa (5.1%), Prosopis africana (5.6%), Euphorbia hirta (4.2%), Khaya senegalensis (6.2%), Newbouldia leavis (8.2%) and Anogeissus leiocarpus (4.5%).

2.3 Experimental Animals

Inbred male and female Swiss albino mice (18-29 g in weight) that were housed in standard conditions of temperature (22 ± 3°C), relative humidity (55 ± 5%), and light (12h light-dark cycle) before and during the study were used in this experiment. The animals were grouped into five (5) groups of 5 according to each plant extracts. They were fed with standard pellet diet (obtained from animal house of Department of Pharmacology and Clinical Therapeutics, Ahmadu Bello University Zaria) and water ad libitum. All the experimental protocols were approved by the Institutional Animal Ethic Committee (IAEC) of the Ahmadu Bello University Zaria and Health Research Extension Act of 1985 (Public Law November 20, page 99-158) USA. The animals received humane care as per the guidelines prescribed by Committee for the Purpose of Control and Supervision of Experiments on Animals (CPCSEA), Federal Ministry of Environment and Forestry, Nigeria.

2.4 Experimental Protocols

Two sets of experiments were carried out. The first set was used to improve an existing experimental model of hemorrhoids mentioned by Elvin (2004), and to validate the same by using pilex granules (PG), Newbouldia leavis extract (NE) which was the plant used widely by traditional healers in North-east Nigeria to treat piles and a combination of both extracts. The protocol was designed to quantify the extent of plasma exudation and to determine the levels of inflammatory cytokines such as TNF-α and IL-6, which are associated with hemorrhoids.

In the second set, the effect of PG, AL, and a combination of some plant extracts were further evaluated by determining the recto - anal coefficient (RAC), severity score, and the histopathological evaluation[4].

2.5 Evaluation of Anti-hemorrhoid Property against Jatropha Oil-induced Hemorrhoid in Mice

Mice of both sexes (20-29 g) were randomized based on their body weights and were divided into 5 groups (G-1 to G-5), with each group consisting of 5 animals (n=5). G-1 animals received PG (Pilex granule) (10 mg/kg) and served as positive control; G-2 animals received AL (100 mg/kg), while G-3, G-4, and G-5 animals received NL, PA and KEP (200 400, and 600 mg/kg b.w; i.p, respectively). Haemorrhoids were induced in all the groups except normal control group, by applying Jatropha oil preparation in five days. A day after induction, all the animals were subjected to respective treatment as assigned to the groups once daily for five days. On the fifth day, 1 h after the treatment, all the animals were euthanized by exsanguinations under deep isoflurane anaesthesia and recto - anal tissues (20 mm in length) were isolated. They were evaluated for the severity score, weighed, and fixed in 10% formalin solution for histological examination.

The RAC was calculated using the formula:

\[
\text{Rectoanal coefficient} = \frac{\text{Weight of recto - anal tissue (mg)}}{\text{Body weight (g)}}
\]

Histological observation of the rectoanal tissue was carried out in order to determine the appearance of inflammatory cells, congestion, haemorrhage, vasodilatation, and medium to high degrees of necrosis [4].

3. RESULTS AND DISCUSSION

Previous research had proved that hemorrhoids are pathological condition, which is characterized by severe vasodilation at the recto-anal region, which leads to inflammation of the surrounding tissues, further leading to secondary complications such as extravasations of fluid into interstitial space mainly due to increased vascular permeability and migration of large quantity of inflammatory white blood cells (granulocytes and monocytes) [5-7].

In the present study, Jatropha oil from seeds of Jatropha curcas (Euphorbiaceae) has been used as an inducer or a phlogistic agent to induce experimental hemorrhoids. In this study, it is possible that Jatropha oil causes inflammation due to the release of soluble factors involving inflammatory lipid metabolites. These factors, alone or in combination with other factors, regulate the activation of resident cells (Fibroblasts, endothelial cells, macrophages, and mast cells) and newly recruited inflammatory cells (Monocytes, lymphocytes, neutrophils, and...
eosinophils) leading to systemic response to inflammation [8-9]. This mechanism explained here was not different from that of the present study (Fig. 1d).

The study showed that the oil from Jatropha seeds was toxic at 1000 mg/kg body weight in the mice (Table 1).

Hemorrhoid induction was on the increase as the dosage was increased, leading to weight loss in mice (Table 2) [10]. The fact that oil from the seeds of Jatropha caused acute inflammation in the rectum of the mice and mortality was witnessed at the dose 1000 mg/kg b.w suggest that at higher dose, the extract is toxic, making it a potential carcinogen (in cancer research ) [10]. In this case, loss of weight in the animals after induction is a symptom of hemorrhoids due to loss of blood and severe inflammation in the recto - anal region of the mice, coupled with anal itching as seen in the animal groups.

AL (Anogeissus leiocarpus), NL (Newbouldia leavis), PA (Prosopis africana), KEP (Khaya senegalensis, Euphorbia hirta, Parkia biglobosa), Results are means ± SEM. The lower the values, the more efficacy of the drug, ™ More efficacy, * Statistical significant at p ≤ 0.05 (One-way ANOVA)

The normal control group showed normal cell architecture of the recto-anal region [11-12] (Fig. 1a). However, intraperitoneal administration of plant extracts of AL, NL, PA, and KEP showed remarkable vasoconstriction of the rectum (Table 3). The greatest healing of the rectum were shown by AL (Anogeissus leiocarpus) and KEP (K. senegalensis, E. hirta, Parkia biglobosa) mixed in 40:40:40 mg/kg ratios, which was evident in the reduction of tissue weights after treatment, and these also confirmed the healing of the mucosa linings of the small intestine of mice by the plant extracts (Fig. 1 a-c). Plant extracts have been used for healing wounds, correct disorders internally and to promote immune responses [12]. The extracts from these must have exerted the same effects on the experimental animals in dose-dependent fashion. These results were comparable with that of the standard control drug (Pilex) at p ≤ 0.05 (one-way ANOVA). All the extracts produced better recto-anal coefficient values than the first line drug Pilex (Table 3).

4. CONCLUSION

Medicinal plants are a source of many biological ingredients which cannot be ignored. The study therefore showed that the extracts of Anogeissus leiocarpus, Khaya senegalensis, Euphorbia hirta, Parkia biglobosa and Newbouldia leavis possess antihemorrhoid properties in mice. But from the study, extracts of Anogeissus leiocarpus and KEP (Khaya senegalensis, Euphorbia hirta, Parkia biglobosa) presented the strongest antihemorrhoid activity in mice than the rest of the plants. These plants can be used as medication for the treatment of hemorrhoids (pile) in traditional medicine, and justified their acclaimed use for treating (of) piles in North-east Nigeria.

The plants thus represent sure sources for (towards) the development of conventional medicines for the treatment of piles other than surgery which normally is very expensive with high risk. However, the precise molecular mechanism behind the antihemorrhoidal activities of these plant extracts and the compounds responsible for the observed activity need to be explored in future studies.

CONSENT

It is not applicable.

ETHICAL APPROVAL

As per international standard or university standard, written approval of Ethics committee has been collected and preserved by the authors.

ACKNOWLEDGEMENT

The authors are grateful to Mr. Ibrahim of the Department of Pharmacology and Clinical Therapeutics, Ahmadu Bello University Zaria, for his help in this work and also the traditional medical practitioners in Bali, Taraba State and beyond, who helped us during the ethnomedicinal survey of these plants especially Mama Daniya Bali (Age 102 years).
