ABSTRACT

**Aim:** The objective of this *in-vitro* study involves evaluating the protective action of the extracts of *L. amara* (LA) (whole fruits including seeds) and *R. emodi* (RE) (rhizomes) at various concentrations on isolated primary rat hepatocytes.

**Methods:** The pulverised dried whole fruits of *L. amara* (LA) and rhizomes of *R. emodi* (RE) were extracted successively with petroleum ether (PE), ethanol (EE) and distilled water (AE) and vacuum dried. These extracts of LA petroleum ether (PE), ethanolic (EE) and aqueous (AE) extracts and RE obtained were subjected to in vitro studies at doses of 25, 75, 100, and 150 µg/ml and silymarin (250 µg/ml) in *CCl₄* (1%) intoxicated primary hepatocytes monolayer cultures. The hepatoprotective action of all the extracts of both plants at different doses was carried out using isolated rat hepatocytes which were subjected to *CCl₄* intoxication followed by estimating/measuring the changes in serum biochemical markers – SGPT, SGOT, ALP, Total proteins (TP), total bilirubin (TB), albumin (ALB) and triglycerides (TGL).

Results: Hepatoprotective activity against CCl₄ was demonstrated in the rat primary monolayer hepatocyte culture using MMT assay with the ethanolic extracts of both plants showing more hepatocyte protective action compared to the aqueous and petroleum ether extracts by reducing the elevated serum marker levels. Alcoholic and aqueous extracts were found to express more protective action towards CCl₄ intoxicated isolated primary rat hepatocytes in a dose dependant manner.

Conclusion: Based on the result, it is suggested that the extract with the most hepatocyte protective action at a dose of 150µg is LA ethanolic extract (viability=88.24%), followed by LA aqueous extract (viability=84.31%), RE ethanolic extract (viability=88.24%) and RE aqueous extract (viability=88.24%) - which are comparable to the reference silymarin with viability at 92.15%. The petroleum ether extracts of both plants showed least hepatic cell viability with LA pet ether extract at 49.02% and RE pet ether extract at 47.85%.

Keywords: Luffa Amara (LA); Rheum Emodi (RE); pet ether extract; alcoholic extract; aqueous extract.

ABBREVIATIONS
LAPE : L.amara pet ether extract.
LAEE : L.amara ethanolic extract.
LAAE : L.amara aqueous extract.
REPE : R.emodi pet ether extract.
REEE : R.emodi ethanolic extract.
REAE : R.emodi aqueous extract.

1. INTRODUCTION

Liver being a vital organ for detoxification, can be injured or suffer functional impairment leading many health disorders and diseases [1]. It is documented that acute hepatitis resembles closely to viral hepatitis with the causative factors being hepatotoxins and con fir mations done using clinical, biochemical and histological findings. Further, as a consequence of many allopathic drug therapies, such as antitubercular drugs, chronic liver diseases like chronic hepatitis, cirrhosis, including vascular lesions and fatty liver get precipitated such that they often resemble viral hepatitis. It is imperative for the chemically induced hepatic injury to be severely modifying or damaging to liver functions, as sequential hepatic injury is related to the type hepatotoxins used on specific animal species for consequential liver disturbances clinically resembling acute hepatotoxicity, like acute viral hepatitis [2,3].

Such hepatotoxicity has been observed with CCl₄ – a most commonly used toxin in experimental studies, as it readily available in pure form, undergoes hepatic metabolism by cytochrome P450 (especially by P450 2E1) causing free trichloromethyl (CCl₃⁻) radicals generation, consequently resulting in direct or indirect in damage to membrane and intracellular lipids, nucleic acids, and other molecules which further leads to toxic hepatic damage with the severity ranging from necrosis leading to triacylglycerol accumulation, cirrhosis and cancer depending upon its mode of application and dose [4,5].

Carbon tetrachloride has been one of the most commonly used toxins in the experimental study of liver disease. In the rat, doses of carbon tetrachloride in the range of several mg/kg body weight produce liver necrosis within one to two hours [6]. Smaller doses in the range of tenths of ml CCl₄/kg body weight repeated several times weekly can produce cirrhosis within a few months [7].

Lipophilic solvents such as CC1₄ might cause liver injury by direct physical interactions with cell membranes. However, the significance of such direct solvent effects is controversial. As allopathic medicines have a cascade of side effects, herbal drugs including have garnered innumerable worldwide attention in treating diverse diseases such as dengue [8], jaundice [9], viral diseases such as HIV-1, SARS related coronavirus, respiratory syncytial virus, including hepatocellular damage in chronic hepatitis B and C [10].

Luffa acutangula.var.amara or L.amara (Cucurbitaceae), is also called karvi turai. Being an annual herb, it's found all over India, but more abundantly in the western peninsula. The fruits are very bitter in taste; the plant is used as a carminative, laxative, tonic for intestines, digestible, used to cure the vata and kapha, biliousness, liver complaints, leukoderma, piles, ascites, tumour and tumorous, useful in bronchitis and asthma and the seed kernals are used to treat dysentery [11,12].
It is also used in treating jaundice when taken in the form of very fine powder through nose, while its seeds show emetic, expectorant, and demulcent properties. The ancient literature also revealed that the plant is significantly used as abortifacient and antifungal agent. The reported chemical examination of *Luffa acutangula* showed the presence of carbohydrates, carotene, fat, protein, phytin, amino acids, alanine, arginine, cystine, glutamic acid, glycine, hydroxyproline, leucine, serine, tryptophan, piperolic acid, flavonoids and saponins [13].

*Rheum emodi* or Indian or Himalayan rhubarb (Polygonaceae) of Indian origin, is considered as purgative, stomachic, and astringent tonic, possesses aperient, emmenagogue and diuretic properties. Root is used as expectorant, appetizer, as powder applied on cuts, wound, and muscular swelling, toothache, tonsillitis and mumps, ulcers [14]. It is used to heal skin sores and scabs. While larger doses are used as laxative, small doses are used to treat dysenteric diarrhoea. [15].

Chinese medicine uses rhubarb for ulcer remedy, as a bitter, cold, dry herb used to “clear heat” from the liver, stomach and blood, also to expel helminths and to treat cancer, fever, upper intestinal bleeding (ulcers), and headache [12,13]. It’s also used in of spring tonics or blood cleansing cures [14,15].

The pulverised dried whole fruits of *L. amara* (LA) and rhizomes of *R. emodi* (RE) were extracted successively with petroleum ether (PE), ethanol (EE) and distilled water (AE) and vacuum dried. These extracts of LA petroleum ether (PE), ethanolic (EE) and aqueous (AE) extracts and RE obtained were subjected to in vitro studies at doses of 25, 75, 100, and 150 µg/ml and silymarin (250 µg/ml) in CCl4 (1%) intoxicated primary hepatocytes monolayer cultures

2. MATERIALS AND METHODS

**Preparation of plant extracts:** The whole fruits of *L. amara* and rhizomes of *R. emodi* were identified and collected from the department of Botany, Sri Venkateshwara University, Tirupati, Andhra Pradesh, India. Both plants were subjected to pulverisation and extraction with petroleum ether, ethanol and distilled water using standard methods of soxhlet [16-18]. The extracts obtained were concentrated and dried under vacuum [19].

**Animals:** Witstar albino rat was obtained from the animal house of Deccan College of Medical Sciences, Hyderabad for this study. The animal was maintained under standard laboratory conditions (12 hrs light: dark cycle, with 60-70 % humidity at 25 ± 2°C) with food and water *ad libitum*. The experiment was conducted after the approval from Institutional Animal Ethics Committee constituted as per CPCSEA guidelines. Protocols for the experiment described below were approved by the ethical board. For this in-vitro study, the albino rat was fasted 18 to 24 hrs with water ad *libitum* prior to the experiment.

**Isolation of rat hepatic cells [20-23]:** To prepare the primary hepatocyte culture, the albino rat was cleaned with rectified alcohol, anaesthetised, followed by dissecting it to expose and cannulate (needle no.25) the portal vein which is then connected to an infusion set. Sterile equipment and glassware was used throughout the experiment. The needle being tied in place, the inferior vena cava was cut below the renal vein and the liver was immediately perfused with Ca^{2+} Mg^{2+} Hanks Buffer solution (at pH 7.4). When the liver turns white after thorough perfusion, the cannula is removed and the isolated liver is minced in a petri dish having Ca^{2+} Mg^{2+} Hanks Buffer solution (HBSS). This was then transferred to a conical flask (having 10ml of 0.75% collagenase in HBSS), stirred with the aid of a magnetic stirrer at 37°C for 10 min. and centrifuged at 50 rpm for 10 min. After aspirating the supernatant, the cells are again suspended in HBSS, followed by washing them twice and counting them using trypan blue dye. The isolated hepatic cells were cultured in sterile culture bottles containing Eagles MEM (having 10% inactivated serum at a density = 0.5 x 10^6 cell/ L. These bottles were incubated for 24 hrs at 37°C under 5% CO2 in a humidified incubator after which their viability was tested. The hepatocytes which accumulated at the bottom of the tubes were observed for growth. Cytotoxicity of both plant extracts of *L.amara* and *R. emodi* were assessed using the primary hepatocyte culture obtained.

Collagenase perfusion technique [24] was utilised to prepare rat hepatocytes, with the cells undergoing many centrifugations so as to be purified and later inoculated at 0.5 x 10^6 cell/ L density on collagen coated plates, which in turn are incubated for 24 hrs. This was followed by exposing the medium to CCl4 (1%) with / without the samples, and silymarin (250µg/ml) being
taken as the reference standard to be tested for their hepatoprotective activity [25, 26]. After 1.5 hrs, the culture medium was collected and tested for hepatic parameters like ALT, AST, ALP, TG, TB, ALB and TP. Cell viability was estimated by trypan blue dye exclusion method [27].

The results were expressed as Mean ± SEM (n=3), statistically evaluated with one way ANOVA and unpaired student t test using Graph Pad Prism 9 software and graphical representation was done using LATEX software. P value < 0.05 was considered statistically significant. P< *0.05<**0.01<***0.001, when compared to the toxicant group as applicable.

3. RESULTS

Preliminary phytochemical tests for LA revealed the presence of the following; LAPE- fixed oils and triterpenes. LAEE & LAAE- flavonoids, glycosides, saponins, sterols, proteins, amino acids and carbohydrates. REPE- triterpenes, REEE- glycosides, alkaloids, tannins, terpenes, saponins and flavonoids. REAE- flavonoids, alkaloids, saponins, terpenes, proteins and carbohydrates.

Treatment of primary rat hepatocytes with CCl₄ resulted in raised SGOT (Serum Glutamic Oxaloacetic Transaminase), SGPT (Serum Glutamic Pyruvic Transaminase), ALP (Alkaline Phosphatase), TB (Total Bilirubin) levels and lowered ALB, TG, TP (total proteins) levels as a consequence of membrane damage and enzyme release – determined by hepatic enzyme levels which are generally found to be elevated in hepatic stress and damage. The cytoprotective activity of the crude extracts of both plants LA and RE showed significant protection against 1 % CCl₄ intoxication in rat hepatocyte culture (Tables 1 & 2) with the ethanolic extract of LA showing more protection (P < 0.001) at nearly all doses followed by the aqueous (P < 0.001) and pet ether extracts (P <0.05– 0.01) being variable with dose. Similarly, significant restoration of hepatic parameters was imparted by the alcoholic (P < 0.001) and aqueous (P < 0.001) extracts of RE with petroleum extracts of both plants showing least protective action (P <0.05–0.01). Maximum hepatoprotective effect was seen with LAEE at a dose of 150µg among all extracts and least with 25 µg of all extracts. The percentage viability of cells was found to be more with silymarin (92.15%) taken as reference, followed by LEAE at 150 µg (88.24%), LAAE 150 µg (84.31 %), REAE 150 µg (82.35 %), REAE 150 µg (80.39 %), while least was observed with CCL₄ (27%).

4. DISCUSSION

Carbon tetrachloride induced hepatic injury involves the metabolic product trichloromethyl (CCl₃·) radical formation as a consequence of CCl₄ metabolism by cytochrome P450 enzymes. This further induces free radical formation leading to hepatic cell membrane damage via lipid peroxidation of fatty acid and/or covalently binding to proteins, DNA or lipids [28,29]. Flavonoids are generally considered free radical scavengers [30].

As in vitro hepatoprotective activity has not been reported on the whole fruit extracts of Luffa amara, this experiment was aimed to estimate the protectiveness of all the afore mentioned extracts in CCl₄ induced hepatic damage. In this study, CCl₄ hepatotoxin reduced cell viability indicative of hepatocytic plasma membrane damage and subsequent release of liver enzymes, evident by increased levels of SGPT, SGOT, ALP and TB in CCl⁴ treated group while ALB, TG and TP were found to be reduced. Incubation of the rat hepatocytes for 1.5 hrs with both the whole fruit extracts of L. amara and rhizome extracts of R. emodi showed effective hepatoprotectiveness in presence of CCl₄ (1%) intoxication comparably at higher doses than lower doses. The overall statistically significant reduction in the elevated hepatic enzymes levels (SGPT, SGOT, ALP, TB) was observed with increasing doses of LAEE, then with REEE, LAAE and REAE. While, the lowered ALB, TG, TP levels were observed to be improved significantly with the same order of extract effects as afore mentioned (i.e., LAEE > REEE > LAAE > REAE). Conversely, least protective effects were observed with the plant extracts in the order LAPE > REPE.

The phytochemical investigations revealing the presence of flavonoids in both plants is indicative of their possible hepatoprotectiveness against CCl₄ intoxication in primary rat hepatocytes, with the possibility of the extracts having antioxidant action [31-33] against free radicals produced during hepatic cell damage – evident by disturbances in the hepatic enzyme levels.

5. CONCLUSION

Thus, based on the result, it is suggested that the extract with the most hepatocyte protective action at a dose of 150µg is LA ethanolic extract (viability=88.24%), followed by LA aqueous extract (viability=84.31%), RE ethanolic extract (viability=88.24%) and RE aqueous extract (viability=88.24%) - which are comparable to the reference silymarin with viability at 92.15%. The petroleum ether extracts of both plants showed least hepatic cell viability with LA pet ether extract at 49.02% and RE pet ether extract at 47.85%. Considering the presence of flavonoids in both plant extracts, hypothetical assumption is conclusive of flavonoids being responsible for hepatoprotective action. However, further investigations on these plant extracts are required for their futuristic usage in the safe treatment of hepatic disorders as well as other pathological ailments.
NOTE

The study highlights the efficacy of “Herbal” which is an ancient tradition, used in some parts of India. The ancient concept should be carefully evaluated in the light of modern medical science and can be utilized partially if found suitable.

ACKNOWLEDGEMENTS

The author extends deep gratitude to Dr. Zakia Abid, Department of Pathology, Deccan College of Medical Sciences for her constant support and encouragement. The author also thanks Owaisi Hospital and Research Centre for providing unhindered infrastructure and requirements to carry out this study.

COMPETING INTERESTS

Authors have declared that no competing interests exist.
