ABSTRACT

Background: The most common fractures seen in senior osteoporotic patients are intertrochanteric (IT) fractures, which are usually caused by a simple fall in the house. The number of old patients is expected to double by 2040 due to an increase in the number of elderly patients with osteoporosis. Understanding key aspects of IT fracture, therapy such as stability, reduction, and the involvement of posterior medial and lateral walls, will aid in implant selection for a better outcome. This fracture interferes with the normal functioning of the body in day-to-day life. Therefore, physiotherapy rehabilitation after surgery is essential to get back to normal functioning.

Case Presentation: A 55-year-old male patient who came with complaints of pain and swelling in right hip, unable to walk. Patient was under the influence of alcohol when he fell from the bed. He experienced sudden and severe pain in right hip and was unable to stand. His relatives brought him to Acharya Vinobha Bhave Rural Hospital (AVBRH), Sawangi, Wardha, Maharashtra for further management. Dynamic Hip Screw was applied for the fixation of Intertrochanteric Fracture. Further on rehabilitation was started, which aimed to restore mobility, regain full range of motion and develop muscle strength.
Conclusion: The Intertrochanteric fracture of femur is a form of fracture with a high occurrence. The above case presentation concludes that a traditional surgical procedure combined with timely planned physiotherapy rehabilitation contributed to progressive improvement in functional goals, which is an important factor in achieving a good recovery in such post-operative cases.

Keywords: Intertrochanteric fracture; Dynamic Hip Screw (DHS); physical therapy.

1. INTRODUCTION

Most common fractures seen in senior osteoporotic patients are intertrochanteric (IT) fractures, which are usually caused by a simple fall in the house. The number of old patients is expected to double by the year 2040 due to an increase in the number of elderly porotic patients. Understanding key aspects of IT fracture, therapy such as stability, reduction, and the involvement of the posteriomedial and lateral walls, will aid in implant selection for a better outcome [1]. Mortality and morbidity following femur intertrochanteric fractures appear to be higher than previously thought. Although younger patients have better functional outcomes, but also can be achieved in the eighth and ninth decades of life and the group of stable intertrochanteric fractures, early operation and the use of internal fixation can reduce mortality and morbidity while improving functional outcomes [2]. Skeletal traction can hasten the healing of an unstable intertrochanteric fracture, resulting in less complication and generally good functional outcomes. In the treatment of IT fractures of the proximal femur, the dynamic hip screw is well recognised. In 1989, Boyd and Griffin suggested classification of type I and type II intertrochanteric femur fractures. Recent studies suggest that Dynamic Hip Screw is a safe, acceptable, and reliable fixation approach for intertrochanteric femur fractures. The goal of this study is to see how physiotherapy rehabilitation works post-surgery for Intertrochanteric fractures [3].

People who suffer from these types of fractures are on average 52 years old [4]. The major cause is medium or high-energy trauma where the proximal end is subjected to increased stresses. With the low forces experienced during trauma, the main pathogenic cause for the older group of patients is bone fragility due to osteoporosis [5-6].

Females accounted for 60.86 per cent of all eligible elderly people. Accidents involving electric bikes accounted for 32.42 per cent of all injuries, with 39.62 per cent resulting in high-energy injuries [7]. The gold standard treatment for such fractures is Dynamic Hip Screwing (DHS) and only choice fortreating complex fractures These fractures have a major effect on the life and wellbeing of individuals. Since surgical fixation, these people are said to be expected to return to work after 6-8 months [8].

The emphasis of this research is on the type of physiotherapy this patient can obtain. This case report aims to review the latest protocol for the recovery of 55-year-old male patient, a chronic alcoholic who fell out of the bed under the influence of alcohol, had an Intertrochanteric fracture that has been surgically repaired, with the goal of providing some advice, especially on four key topics: hip joint range of motion exercises, immobilization, weight bearing, and continuing rehabilitation [9].

2. PATIENT INFORMATION

A 55-year-old male, retired engineer, right sided dominant, married since 34 years who is a chronic alcoholic fell down from the bed under the influence of alcohol. He started complaining of severe pain and swelling in the right hip and was unable to walk. Patient was under the influence of alcohol when he had a fall from the bed. He experienced sudden and severe pain in right hip and was unable to stand. The pain was aggravated by movement and relieved by immobilization. Then he was taken to local physician where he took indigenous treatment but had no relief. Then his relatives took him to Acharya Vinobha Bhave Rural Hospital (AVBRH), Sawangi, Wardha, Maharashtra. X-ray was done and was diagnosed with Intertrochanteric fracture of femur where he was advised for surgery. Dynamic Hip Screw was applied for the fixation of Intertrochanteric Fracture. Post-operatively patient was treated with drugs, IV fluid, antibiotics and medications. He had a past history of Diabetes mellitus. Then the patient was recommended for physiotherapy for rehabilitation, which aimed to restore mobility, regain full range of motion and develop muscle strength.
3. CLINICAL FINDINGS

The patient was conscious and well oriented. Prior oral consent was taken from the patient before the physical examination. The patient was examined in the supine position. On inspection it was observed that right leg was slightly abducted, slight externally rotated, the knee was in the 20 degrees of flexion, both ankles were slightly plantarflexed, the pillow was kept between both the legs. On palpation local temperature was slightly raised, diffuse swelling was present around the right knee, no marked oedema, no marked muscle wasting, grade 2 tenderness was marked over anterior joint line and greater trochanter also severe pain was present at the operative site, VAS Scale score was 9/10 on activity and at rest was 6/10.

4. MEDICAL MANAGEMENT

Patient visited AVBRH with the major complaints of pain and swelling around the hip joint, due to which he was admitted. X-ray of lower leg revealed Intertrochanteric fracture. An ice pack was advised for swelling and right leg was immobilized. After 5 days he underwent surgery.

Preoperative medications – Inj. Tramadol 50 mg TDS, Tab chymotrypsin TDS, Tab Zerodol SP BD, Tab calcium, Sachet Vit D3. 650mg TDS, Tab Pantoprazole 40mg OD, Inj. paracetamol 100ml SOS.

Post-operative medications - Tab calcium 500mg BD, Tab cefixime 200mg BD, Tab Dolo Examination Findings: MMT cannot be assessed as post operatively hip joint was immobilized for a week.
5. THERAPEUTIC MANAGEMENT

The patient was referred to the physiotherapy department. The rehabilitation was planned in phases and administered accordingly.

6. POST-OPERATIVE MANAGEMENT

Phase 1 (0-7th day): Initially cryotherapy thrice a day is advised with application of modality (IFT for minimum of 10-12 minutes for at least a week) to reduce pain and swelling. Breathing exercises taught to increase lung capacity postoperatively. Active assisted bed mobility exercises taught for ankle and knee joint which includes ankle toe movements, static quads, static hams, static glutes to strengthen isolated muscle groups, also heel slides and bed rolling, hip joint is immobilized for 1 week. Patellar mobilization started.

Phase 2 (8th – 14th day): Exercises taught in the first week will be continued in addition to that CPM was applied to restore initial hip and knee movements, with passive range of motion exercises for hip and knee. Continuing patellar mobilization with inclusion of stretching for Lower limb. Isometrics were continued for quadriceps, hamstring and glut. Non-weight-bearing aerobic exercises were given. Modalities for pain and inflammation were used when required. Soft tissue mobilization was given manually.

Phase 3 (14th – 21st day):

Most of the exercises were continued as in phase 2. Partial weight-bearing was initiated from the 3rd week. Partial weight-bearing started using crutches. Isometrics and strengthening exercises for lower limb were given with partial weight-bearing for lower limb muscles. Stretching exercises for hams, quads and other lower limb muscles were continued. Weight-bearing was increased progressively.

7. DISCUSSION

To the author’s surprise, there is dearth of literature regarding physiotherapeutic management week wise according to the condition which differs from patient to patient. In the above case it is been seen that after fixation of DHS, therapeutic management varies as per the age and the pre-op rehabilitation. The patient didn’t had good strength prior so it took more of the time to strengthen the lower limb muscles and so on. Further on protocol was set according to the available range and pain and also the healing process which showed delayed due to the age factor. Study done by Yu J, Zhang C in the year 2015 presents that patients operated with the use of different internal fixators has different treatment protocol according to the level of fracture, dislocated or mal-united, etc. Research conducted from 1989 to 2011, only 15 cases followed up on for an average of 17 months (2–58 months) using eight different fixation devices. An initial mortality rate of 13% (n = 2) was observed. All of the females (n = 8) had low energy trauma, while the majority of the males (83 percent; n = 5) had high energy trauma. In 20% of cases, the diagnosis was delayed or missed. As a result of the physiotherapy treatment, the patient's range of motion has expanded, and he or she has begun to bear weight on the limbs. The key goals were patient education, secondary problem avoidance, and maintenance, as well as quadriceps and hamstring muscle strengthening. The patient has resumed a regular walking pattern and has experienced pain reduction, as well as the ability to walk without assistance. Physiotherapy management is an essential component of rehabilitation in order to return to a normal routine and improve quality of life.

8. CONCLUSION

The IT fracture is a form of fracture with a high occurrence and is a complicated fracture to treat. IT fractures are well-managed with DHS fixation, which offer excellent anatomical reduction, preserve articular congruity, facilitate early mobility, reduce post-traumatic osteoarthritis, and achieve optimum function.

The above case study concludes that a traditional surgical procedure combined with timely planned physiotherapy rehabilitation contributed to progressive improvement in functional goals, which is an important factor in achieving a good recovery in such post-operative cases. Preoperative preparations must be thorough and comprehensive. Early mobilization and a stronger practical performance are facilitated by well-maintained articular congruity and stable fixation.

CONSENT

Written and Oral informed consent was obtained from the participant included in the study.
Additional informed consent was obtained from all individual participants for whom identifying information is included in this manuscript.

ETHICAL APPROVAL

It is not applicable.

COMPETING INTERESTS

Authors have declared that no competing interests exist.
