ABSTRACT

The most significant thing in a mental health disorder is its prevalence. Here we compare the consequences of pandemics on people’s mental health with the recordings of ASD & PTSD in the last forty years; we will prove that they are primarily different. The symptoms of mental disorders differ; therefore, the chances of good treatment differ are significantly less. We tend to cancel some chances of a new mental disorder, considering a new one can emerge from this pandemic. We have to determine the extent of what pandemics are doing to one’s mental state. The author planned medical care for immediate support.

"Health is a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity." Thus mental health is more than just the absence of mental disorders.

Mental health is a state of mind in which he can realize his capacities and abilities, cope with stress, and have optimal productivity.

Mental health is essential for a person for his own sake and the collective good of society; for good mental health, a person should be content with his life. Thus the prevention and restoration of mental health are essential for individuals and society. Multiple social, psychological, and biological factors are responsible for knowing a person’s mental health.

Social factors, stressful conditions in the workplace, gender discrimination, and unhealthy lifestyle

are also responsible for the deterioration of mental health. There are specific psychological and personality factors that make people vulnerable to mental health problems. Biological risks include genetic factor.

Keywords: COVID-19; mental health; stress disorder. COVID-19: anxiety; psychological impact; stress; virus canceling medical appointments; depression; lockdown; pandemic; psychological flexibility.

1. INTRODUCTION

Stress, worry, and fear are common answers to any problems individuals face and, of course, when faced with the grand unknown. Thus it is highly expected that people are facing fears in the pandemic [1].

Complimenting the fears of getting covid there is the added stress of very significant changes in our lives, as our movements are restricted for slowing down the virus. The new life of working in the safe confinement of our home, homeschooling children and of course the lack of in-person contact with our family members and peers is adding to this, we must look after our mental, and our physical, health [1].

People everywhere were either sitting jobless or working from home [1]. This led to depression and mental stress, along with phobia adding to this was the limited social interactions. Fearing for going out to work and fear to use public transport were the main reasons for increased stress. Students were worried about their careers, business people were losing business, and even marriage added stress [2].

2. EFFECT OF PANDEMIC

The pandemic has affected the world at a hazardous rate leaving it shattered. The cases have risen sharply since then. The start of covid was followed by strict lockdown in various parts of the world, such as no travel, closing of schools and offices, and commercial activities. Rigorous quarantine to reduce covid [3]. pandemic brought along various problems that were very new to society. Along with a very high death rate, this pandemic has brought many psychological, emotional, and physical problems. Globally all the scientists have exhausted themselves trying to end this godforsaken pandemic. The recent research focuses more on the clinical covid pandemic, the chances of survival, genes of virus, and drug options. There was significant growth in anxiety, insomnia, and distress cases across nations. Despite this, the psychological impact of covid has not gotten enough attention [4].

We found four varieties of major problems faced with patients with mental health problems through this pandemic. (1) some conditions that are often found in someone with mental health disorders that is (cardiovascular and pneumonic pathologies, diabetes, obesity, etc.) may be a risk for covid infection.; (2) age –people in the age group who are at risk of getting covid; (3) financial difficulties.

In addition, the psychological state tending system is additionally exposed to different tending systems. Additionally, a particular range of structural things build the medicine establishment notably vulnerable: several beds are closed, wards have high numbers of patients, psychological state-society facilities are closed, and medical faculty are short-handed and not trained sufficiently to handle a pandemic of this magnitude. People with mental disorders also face problems in medicine [5]. To keep up with medical care during the pandemic, several steps can be taken along with opening the "covid unit."

These things are beneath the twin oversight of a medical specialist associate degree. In infection specialists, all new patients are placed directly into covid wards. The nursing employees receive important coaching, daily covid tests, and no mental support. Meeting your family physically is prohibited; instead, you have to shift to virtual platforms [6]. When the number of people admitted is at maximum, some specific cases are aided with a home visit. Supporting patients when they return to their homes and assisting them in addressing this increases the risk of mental disorders. The entire societies, especially psychiatrists, are distressed for people with mental health disorders; however, a daily follow-up can decrease the risk of suicide. New-education strategies; developing support platforms may help to reduce these risks.
3. ROLE OF DOCTORS

Doctors have a prominent role in barrier issues and confinement of individuals, and similarly to stop the mental health risk of confinement, physical workout, stress management, social interaction, they must be trained to deal with early symptoms of depression as a result of this Chinese people are mentally tormented [7].

The covid 19 pandemic exhausted the medical system; the assessment is essential. In Italy, a Regional Emergency Committee (REC) was established, so the regional health system was organized, with three hospitals elite as hubs for trauma care. This study aimed to get the results of these changes made in regional care, examination of mental health before and after the pandemic [8].

We have some data of patients' mental health before the covidpandemic and the one recorded throughout the covid pandemic from identical hospitals. Age group information and medical care utilized (Advanced Life Support-ALS, Basic Life Support-BLS), injury mechanism, injury severity score (ISS), revised trauma score (RTS), and treatments got by the patient along with their survival possibilities were recorded. Covid testing was done with body swabs and chest ultrasound or X ray [9].

Covid 19 affected the drugs of pa patients who have suffered from severe trauma. There was a rise in the number of trauma patients admitted to elite facilities, but with proper care, the result was found to be satisfactory. The covid-19 has been highly disastrous to people worldwide; however, its impact on different sequences and injuries has been variable [10]. To find out the consequences of covid on significant injuries, we have compared some data of 2003 with 2020. The records of trauma written in tertiary care metropolitan hospitals were analyzed. Patients who had a significant traumatic injury in 2001-2003 and those who suffered in 2018-2020 were retrieved and re-analyzed. Patient characteristics, injury mechanism, admitting service, and emergency department (ED)/hospital lengths of keep (LOS) were recorded. Major trauma cases. The 2003 respiratory disorder and 2020 covid pandemic originated in the metropolis. This gave a base for the suggestions for future pandemics.

Centers for healing trauma and resource allocations are not just when the pandemic starts but way before it happens as a shield is also very important [11]. Isolation is very closely related to depression, anxiety, and psychological decline [11]. It reduces resilience factors like self-esteem, feeling valued by others, or having any purpose. However the government management of individuals presents yet another problem.

4. DISEASE MANAGEMENT

All new entries are placed in quarantine for three days; nurses receive a surety of employment, daily medical check-ups, and psychological support. Family visits are strictly prohibited and shifted to virtual platforms. At the height of highest hospitalization, like those who need some professional care equipment, or specific cases requiring high level of management, these cases are managed with case visits, therefore, for patients who come back home from isolation and needs to shed off the experience of confinement, they are susceptible of getting various mental health issues. A daily follow-up is possible through various virtual platforms and can prevent cases of suicide. Psychiatrists have a vital role in knowing their patients in confinement to prevent the risks that are eminent in confinement: a normal circadian rhythm, working out, and management of stress interference reduce the chances of addiction and stress disorder, as a result of their chances was high among the regions of China is that the very most ill with the pandemic [11].

Psychological care faces too much trouble and would not shy away from a reorganization and may need a complete support system for emotional disorders because of the confinement of a significant part of the population.6

The covid 19 exhausted a large part of health resources worldwide. This study aimed to find out the results of this reorganization.6

A coherent study was conducted in LTR. (September one to Nov nineteen, 2019) with those recorded throughout the pandemic (February twenty-one to May ten, 2020) within constant hospitals.6 Data of different age groups, pre-hospital care (ALS and BLS), style of transportation, injury mechanism, abbreviated injury score, injury severity score (ISS), revised trauma score (RTS), survival outcome of patients, admitted to centers of trauma. Tests for covid were performed using body swabs and CT scans.7
The COVID-19 pandemic has been massively harmful to people around the world. It has been different on different diseases to get the consequences of COVID-19 on people. Major trauma cases born by throughout each the height of the 2003 disorder and 2020.

COVID-19 pandemics in town suggest a trend significantly arising for the end of the day pandemic. If similar findings unit seen at entirely different trauma centers [11].

Additionally, the isolation of the management of interns poses a different problem for older individuals. The has been great concern about the impact of covid. Pandemic and restrictions also had a very negative impact on children; this can cause some permanent damage to the minds of children and adults [11].

There has been a worry about how this pandemic will leave us. One exception is the case study from covid-19. As the knowledge used by the study is of before pandemic, it cannot answer the state of mental health in the pandemic. The collecting of monthly information from people of different ages and varieties gives a single chance to look at what this pandemic has done.

Between March 2020 and 2021, we have seen a slight decline in students’ cognitive functioning as they have been at home for two years.10 (Most adolescents came back into high school in march 2021. The symptoms reported by parents and students were stable over time, but during this time, adolescents were isolated and could not see the doctors.

On the other hand, we have seen a lot of changes in parent-reported syndrome. (according to pandemic restriction in India). This was prevalent in kids aged 4-10 years. On the other hand, the kids in puberty were reported normal.

These results need more proof, but two principal components were pressure from Peres and family stress. It should be noted that a bunch of pre-teens needed to talk much more with their peers when covid was at its peak [11]. Stress has been additionally high amongst the patients.

At these times, when parents were managing work and home and taking care of their kids simultaneously, most parents felt that they couldn’t do this sufficiently.

Parent’s stress was high for low-income families, and kids here were prone to mental disorders.

These results are hazardous as we know the association of parental stress along with hostile family surroundings on kids [1].

Kids with all these factors were reported to be prone to neurological disorders and low-income families. But the association with these factors and deteriorated mental health was prevalent well before the pandemic.

The growth in symptoms may not be evident, but we saw its significance for SDQ in march 2020 as restrictions increased.8 For kids in low-income families, the symptoms increased.

The co-space finding, as proved by others like a study from the UK National Health Service that raised worry over mental health in 2020 compared to 2017, significantly for boys aged 5–10 years and with families who were struggling money-wise [11].

The symptoms we find as the parents told and as the kids say were again proved in some school-based studies [12].

The anxiety reported by kids themselves was also significantly higher fact it was the highest in the pandemic. Lockdown meant most children were not at school; we have to examine thus the state of the mental state of all age demographics with or without a pandemic, compare those, and work towards it accordingly [13].

This article confirms the stress and other psychological problems faced by people in India during the pandemic; some ideas were made on how to manage stress at the macro and micro levels. 6lt was found out that mental health help is required during a pandemic, which is essential for the better mental health of society as a whole. The government is taking several solutions, like tole free helplines and virtual counseling for patients. Similarly, resources for managing stress are available in official government websites [13-21].

The studies revealed that people with insurance policies against covid are less prone to stress than those without one. Thus, the government ensures that insurance companies provide
diagnostic and treatment coverage for covid. This will ensure the hope of leading a worry-free life in the future. Further, the insurance companies must be honest with their plans.

The public lack of trust toward the government was one of the significant causes of stress in the pandemic thus, an effort by the authorities towards the reaction of public towards their policies must be reviewed. This will ensure that public understands them and thus ensuring there policies. People's thinking of the dangerousness of a disease is also shaped by government and media. Thus a great care should be taken while communicating.

5. CONCLUSION

Humans always need social interaction in their lives. As proved in the study social support is of much importance to deal with these kind of situations. Thus public heath department must help on community health. It is evident that external sources are not in our hands thus we need to control what we can control. We need this helps to be resilient, hopeful and positive during this tough time. Hence the institutes of government, schools and NGOs should invest in development of positive growth.
