ABSTRACT

Objective: This study aimed to assess effect of general health state, therapy satisfaction and INR control on quality of life in warfarin patients.

Methods: A cross-sectional study using a newly developed and validated research tool was conducted in patients on warfarin. Data was collected by convenience sampling method. Descriptive, comparative, and inferential statistics were used by Statistical Package for the Social Sciences (SPSS) ver. 24 to determine the sociodemographic correlates of warfarin knowledge in warfarin patients.

Results: Among total 275 studied warfarin patients, the majority of the studied warfarin patients were females than males (n=184, 62.4%, and n=111, 37.6% respectively). A total of 188 (63.7%) patients were satisfied from their healthcare providers while 107 (36.3%) were not satisfied from healthcare providers. Around 128 (43.4%) of the patients were actively managing their disease while 167 (56.6%) of the patients were not able to actively manage their disease.

Conclusion: These results confirmed that overall study participants had moderate effect of QoL on general health state, therapy satisfaction, and INR control among patients on warfarin.

Keywords: Warfarin; general health state; therapy satisfaction; INR control; QoL.
1. INTRODUCTION

Health literacy deals with various different aspects like understanding a disease state, empowerment about a disease, ability of a patient to comprehend, appraise and best use of health information to manage his/her disease and therapy and make appropriate healthcare decisions [1]. In literature, few preliminary studies provide evidence that indicate effects of health literacy on patients’ overall disease management, their awareness about disease and therapy outcomes and patients’ medication adherence. It is also reported that patients with insufficient or inadequate health literacy levels often result in poorer disease outcomes, complex health complications and worsening of the diseases [2-3].

Warfarin always requires frequent and careful laboratory monitoring to minimize or avoid bleeding complications and to obtain optimum therapy due to its narrow therapeutic window [4-8]. It also has high inter- and intrapatient variability, and is only effective if its therapeutic range is maintained. If its blood levels are above or below its therapeutic window, it exhibits greater risks of bleeding and thrombosis [6-9]. Warfarin is amongst the most frequently used oral anticoagulant, that is often prescribed to control and prevent various thromboembolic diseases like venous thromboembolism, stroke, atrial fibrillation, and valvular heart disease [7-9].

Quality of Life (QoL) is not only measured in healthy individuals but also in patients to estimate the overall health status of the society which ultimately helps in designing and implementing healthcare policies to improve the overall health status of the society [10-12]. The QoL is a multi-dimensional model generally used to observe the impact of health status on individuals’ quality of life [13,14]. The WHOQOL-BREF tool is comprised of four different domains named physical, psychological, social and environmental domains [10]. Several studies across the globe are evident in the literature regarding the impact of warfarin therapy on disease outcomes, warfarin therapy duration and its anticoagulation control, the association of warfarin therapy duration and INR, treatment satisfaction and association of knowledge and beliefs with anticoagulation control [13-20]. This study aimed to assess effect of general health state, therapy satisfaction and INR control on quality of life in patients on warfarin.

2. MATERIALS AND METHODS

This was a cross-sectional study done and a self-administered questionnaire was employed. The study subjects were screened for inclusion and exclusion criteria. For inclusion criteria, participants above 18 years, non-pregnant women and those who gave consent were included in the study. For exclusion criteria, those who did not meet the inclusion criteria were excluded from the study. At first, information sheet was handed to patients and informed consent was taken. The questionnaire was delivered personally to the patients by the researcher who also collected them back after they completed the study. The sampling method employed was convenient sampling. Sample size was calculated using an online sample calculating tool, www.raosoft.com. Content validity of the questionnaire was checked before start of the study. Reliability of the questionnaire was assessed using Cronbach’s alpha which is the most common tool to be used to measure internal consistency. Cronbach’s alpha obtained was 0.073.

2.1 Statistical Analyses

Percentages and frequencies were used for the categorical variables, while means and standard deviations were calculated for the continuous variables. Spearman's correlation coefficient was used to evaluate correlations and effect of various variables on overall QoL of the studied warfarin patients. Data from the research questionnaire were analyzed using Statistical Package for the Social Sciences (SPSS) version 24.0.

3. RESULTS AND DISCUSSION

Fig. 1 represents the demographic data of the study participants. According to the results obtained, there was a total of 295 participants with more females than males (n=184, 62.4%, and n=111, 37.6% respectively). One hundred and eighteen (40.0 %) were less than 30-years whereas one hundred and seventy-seven (60.0%) were above 30-years. Ten (3.4%) had a primary level of education and 285 (96.6 %) had a higher level of education. One hundred and three (34.9 %) had comorbidities other than CVDs and one hundred and ninety-two had no comorbidity. Fig. 1 describes the detailed demographic parameters used in this study.
Table 1 shows the key responses of warfarin patients about general health state, health literacy and INR control. A total of 188 (63.7%) patients were satisfied from their healthcare providers while 107 (36.3%) were not satisfied from healthcare providers. Around 128 (43.4%) of the patients were actively managing their disease while 167 (56.6%) of the patients were not able to actively manage their disease. A total of 147 (49.8%) of the patients were satisfied from their healthcare system while 148 (50.2%) of the patients were not satisfied from their healthcare system.

Fig. 2 presents the mean QoL scores for all the four domains of the WHOQOL-BREF among the study respondents. The mean score for the physical health domain was 62.44±15.36. Mean scores for the psychological domain, social relationship domain, and environment domain were 67.84±15.54, 64.27±26.28 and 63.45±17.66 respectively.
Table 2 shows the Spearman Rank order correlation coefficient scores between QoL domains and the obtained scores of the research tool. The association coefficient between WHOQOL-BREF four domains (physical, psychological, social and environment) vs total scores of the research tool were 0.134, 0.147, 0.162 and 0.111 respectively. There was statistically a significant correlation ($p < 0.05$) observed between the psychological domain and social domain of WHOQOL-BREF vs scores obtained from the research tool.

Assessment of the general health state, therapy satisfaction, and INR control is crucial to determine the exact health states of warfarin patients. According to the WHO’s social and psychological determinants model for chronic disease patients, the social and psychological aspects of the patients are important to be evaluated in order to diminish healthcare and health state inequalities. Indeed, the general health state, therapy satisfaction, and INR control determination can help warfarin patients to understand well and deal fairly with their healthcare issues and improve their QoL.

Our study results emphasized that good healthcare literacy regarding patients’ health state can further help patients on warfarin in improving their therapy adherence, enhancing treatment outcomes, and improvement in treatment satisfaction. A profound health literacy can also result in minimizing treatment
complications and to avoid adverse drug reactions and drug or food interactions among warfarin patients. Furthermore, life style modifications and treatment adherence can also act synergistically to further improve the patients' overall QoL. This study had two major limitations, time and less sample size. More accurate and precise findings could be obtained at a broader level if a study is done at a large sample size and for a longer period of time.

4. CONCLUSION

In conclusion, our study highlights that overall study participants had average to moderate general heath state, moderate therapy satisfaction, and controlled INR. The present study also showed a positive and statistically significant association between health state, treatment satisfaction and QoL.

ACKNOWLEDGMENT

The publication was supported by the deanship of scientific research at Prince Sattam Bin Abdulaziz University, Alkharij, Saudi Arabia.

CONSENT

For inclusion criteria, participants above 18 years, non-pregnant women and those who gave consent were included in the study.

ETHICAL APPROVAL

It is not applicable.

COMPETING INTERESTS

Authors have declared that no competing interests exist.
