ABSTRACT

Objectives: To evaluate the frequency of reactive and clonal thrombocytosis based on age, sex, clinical findings, and severity of thrombocytosis. We also highlight the determination of hematological parameters for the diagnosis of these disorders required the management of thrombocytosis to reduce the morbidity and mortality rate.

Methods: This descriptive experimental study was conducted in the Diagnostic and Research laboratory, Peoples University of Medical and Health Sciences, Nawabshah and department of Pathology, from July 2017 to June 2018. Total 325 patients including 260 patients with reactive thrombocytosis and 65 patients with clonal thrombocytosis, their age ranged between 12 and 45...
The thrombocytosis is one of the hematological disorders characterized by increased platelet count of more than 45,0000 per cubic mm in peripheral blood can be divided into primary or essential or clonal and secondary or reactive types [1]. The platelet in secondary thrombocytosis acute phase reactant increases in response to various stimuli such as inflammatory cytokines including interleukin-6,11 and 1, tumor necrosis factor beta, colony stimulating factor and thrombopoietin more frequently seen in inflammation due to the infection or tissue injury caused by trauma or surgery, cancers and iron deficiency anemia [2].

Patients usually in secondary thrombocytosis due to acute and chronic bacterial and viral infections present with fever, tachycardia, mild anemia, rarely hepatosplenomegaly, low hemoglobin, increase ESR, total leucocyte count less than 50,000 /cm with neutrophilia and increase platelet count above 50,000 per cubic mm that can be normalized after treatment of conditions that cause thrombocytosis [3].

The increased erythropoietin level that is homologous to the thrombopoietin regulating the platelet production causes thrombocytosis in iron deficiency anemia and patients present with sign and symptoms of anemia, low hemoglobin, decrease serum iron, ferritin and increased iron binding capacity along with thrombocytosis [4].

Clonal disorders or primary thrombocytosis seen in chronic myeloid in contrast to the reactive type is caused by clonal expansion of hematopoietic progenitor cells in bone marrow due dysregulation of physiological mechanism that control the production of platelet is caused by genetic mutations including calreticulin, Basic cluster region- Abelson and thrombopoietin receptor genes [5,6]. Clonal thrombocytosis or primary type is common in adults than children, slow in onset and patient usually present with dizziness, headache, bleeding tendency and thrombocytosis acute phase reactant increases in response to various stimuli such as inflammatory cytokines including interleukin-6,11 and 1, tumor necrosis factor beta, colony stimulating factor and thrombopoietin more frequently seen in inflammation due to the infection or tissue injury caused by trauma or surgery, cancers and iron deficiency anemia [2].

The frequency of thrombocytosis was higher in clonal thrombocytosis than the reactive type.

1. INTRODUCTION

The current descriptive experimental study was conducted in the Diagnostic and Research laboratory, Peoples University of Medical and
Health Sciences, Nawabshah and department of Pathology, from July 2017 to June 2018. We selected 325 patients, age ranged between 2 and 65 years, 225 males and 100 females coming from various cities, villages of district Shaheed Benazirabad, at reception of diagnostic and research laboratory of PUMHSW, Nawabshah. The clinical history and physical examination of all these patients were performed and blood and bone marrow biopsy samples were collected for routine laboratory testing such as complete blood count, examination of blood and bone marrow smear to detect thrombocytosis among the patients with hematological and non-hematological disorders. Iron profile was required for the diagnosis of iron deficiency.

### 3. RESULTS

A total of 325 patients with their mean age 33.5±31.5 and male to female ratio of 2.2:1 were included in this study. These patients were diagnosed with a hematological and non-hematological disorders based on clinical manifestations such as fever with cough, burning micturition, diarrhea, body ach, head ach, pallor ness, splenomegaly, and, history of splenectomy.

The mean value of Hemoglobin (g/dl) 11.5 ± 1.5, Total leucocyte (Count/cumm) 21200 ± 5000, Neutrophils (%) 85 ± 5, Lymphocytes (%) 10 ± 5, were found in this study. Among the patients with urinary tract, gastrointestinal tract, respiratory tract infections, and iron deficiency anemia.

4. DISCUSSION

The importance of comparison and risk of complication among the patients with reactive and clonal thrombocytosis were evaluated by different studies such as among the children at the age of two years, frequency of secondary thrombocytosis due to infection overall was 37 to 78% and respiratory tract infection was 60 to 80% as observed by the Ozcan et al. and wang JL et al [10,11]. They observed that the most common cause of secondary thrombocytosis among the children are acute and chronic viral infections and clinic hematological findings among the 810 adult patients with secondary thrombocytosis were fever, tachycardia, weight loss, anemia, leukocytosis with neutrophilia, and platelet count above 50,0000 per cubic mm as detected by wang JL et al. and Rose et al [11,12]. Secondary thrombocytosis due to release of cytokines such as interleukin, IL-3, IL-6, and IL-11 which stimulate megakaryopoiesis, increasing the number of platelets as mentioned by Kulnigg-Dabsch et al [13]. In inflammation processes, the production of IL-6 in macrophage fibroblasts increases, together with a simultaneously-observed increase in the concentration of the granulocyte growth factor GM-CSF. Inflammatory factors also lead to the reduction in the level of hemoglobin, by disturbed erythropoietin production (due to disturbances in iron management and inhibition in suppression of erythropoietin), or shortening their life. There is a direct relationship between the number of platelets and the value of white blood cells, as well as an inversely-proportional relationship between the intensity
of thrombocytosis and the severity of anemia. Post splenectomy reactive thrombocytosis and uncontrolled reactive thrombocytosis among the patients with idiopathic thrombocytopenic purpura after splenectomy was treated with thrombocytopenia were detected by Khan PN et al [14]. Das SS et al [15], while reactive thrombocytosis due to the iron-deficiency anemia leading to rare complication such as Raynauds phenomena among the male patients was observed by khan F et al16& Subha R et al [17] stated that thrombocytosis among the patient with colon cancer after surgical resection of colon developed pseudo-hyperkalemia due to the increased release of potassium during the clotting process, other causes for pseudo hyperkalemia include a tourniquet, ethanol containing antiseptics, cold temperature, time delay in sample transport, contaminants like potassium-containing intravenous fluids, potassium salts of tube additives and heparin-induced WBC lysis for reverse pseudo-hyperkalemia. The frequency of reactive thrombocytosis due to infection and tissue injury was 91.8% while clonal thrombocytosis was 8.2% among the 10 patients was founded by Syed NN et al [18]. Beatrice JM [19] stated that among the two types of thrombocytosis such as primary and secondary, the primary as myelo-proliferative disorders rare in children seen in chronic myeloid leukemia, polycythemia, and essential thrombocythemia also called clonal disease derived from a multipotent hematopoietic cell. They also described the signs and symptoms of disease occurring due to the stimulation of the megakaryocytic line, without significant granulocytic and red blood cell stimulation and in these patients, megakaryocytes production takes place due to increased sensitivity to the thrombopoietin stimulation. The average age of children in these disorders is 11 years with increased platelet count leading to bleeding and thrombotic complications observed by Chiarello P et al [20]. Chronic myeloid leukemia with extreme thrombocytosis that is above 10,00000 /cmmm leading to syncope and myocardial infarction and features of essential thrombocytosis in peripheral blood and bone marrow smears among the patients with chronic myeloid leukemia were detected by Rawa I et al [21] and Bychu YJ et al [22]. The platelet dysfunction in the form of normal platelet aggregation with ADP, collagen, and epinephrine and failure of aggregation with ristocetin among the patients with chronic myeloid leukemia was founded by Olga MA et al [23]. Reported portal vein thrombocytosis among the 32 years old male diagnosis with CML who head anemia, leukocytosis and thrombocytosis while platelet indices such as high mean platelet volume and platelet distribution width along with platelet count more than 50,0000 /cm were found in primary or clonal thrombocytosis seen in chronic myeloid leukemia and platelet count less than 50,0000 /cmmm with low MPV and PDW were found in reactive thrombocytosis as reported by Saud BA et al [24].

5. CONCLUSIONS

The following conclusions and suggestions were made from the above study

1. The reactive thrombocytosis was more common among the children and adults with high frequency of male and female as compared to the clonal thrombocytosis common in adults with a high frequency of male The most common causes of reactive thrombocytosis are infections, after splenectomy and iron deficiency anemia while the cause of clonal thrombocytosis is chronic myeloid leukemia.

2. Mild to moderate thrombocytosis was common in reactive thrombocytosis and moderate to severe thrombocytosis was founded in clonal thrombocytosis seen in chronic myeloid leukemia. However none of our patients was present with neither extreme thrombocytosis nor any thrombocytic complication was detected in any patient.

3. Further studies are required to detect thrombocytic-complication sn among patients with two major types of thrombocytosis. Hence we advise the physician to treat these patients as soon as possible to reduce the risk of death due to the bleeding and blockage of the blood vessels of vital organs by dangerous thrombi among these patients
